

1. Abstract
2. Introduction
3. Theory and Model Specification

We assume that the count of unigrams x_{ij} in documents for unique unigrams $i \in (1, 2, \dots, I)$ across $j \in (1, 2, 3, \dots, J)$ documents is distributed according to the multinomial. Suppressing i by denoting x_j as the vector $(x_{1,j}, x_{2,j}, \dots, x_{I,j})$, we have the following model:

$$x_j \sim MN(q_{ij}, m_{ij}); q_j = \frac{\exp(\alpha_j + Y_j \theta_j + U_j \Gamma_j)}{\sum \exp(\alpha_j + Y_j \theta_j + U_j \Gamma_j)}$$
